Panda is a Programmable Input/Output (I/O) Packet Architectural Design Environment. Panda allows the user to describe the functional behavior of the data-path architecture by defining one or more ports to generate output events. These events can then be processed by an associated Port Management System to generate a "signature" or sequence of low-level events that can be applied to another functional block or to a device. Panda offers an ability to specify a strict hardware implementation of the packet switching function as well as flexible functionality. Panda allows designs to be optimized using a set of pre-implemented and pre-optimized modules that can be reused for several applications. Trellis is a Programmable Input/Output Architecture Library for the IP Stack. It can be used to generate a Lattice device description by describing the function of an IP stack. A series of modules can be implemented to describe the IP stack, and Trellis will synthesize a Lattice device implementation of the IP stack with a high degree of hardware optimization. This high level of optimization allows the IP stack to be synthesized efficiently and helps to reduce the overhead of designing and simulating at the Lattice CPLD level. The college football scouting combine is in the rearview mirror, and the NFL combine is right around the corner, which means that draft season is still just a few weeks away. NFL.com's Chris Wesseling has an early look at the Denver Broncos' current depth chart and who they might target at certain positions, especially on the offensive line. The Denver Broncos look like they could end up in a position where they're looking to replace some significant contributors. Let's take a look at some of the biggest names that are off the roster and see what the draft options are for the team. For the Broncos, this is another season where they may be looking to improve at the most important position, the quarterback position. Peyton Manning had 82157476af
